Fluid Mechanics 335 – Course Objectives

- 1. In all problems worked this semester, students will **report, carry, and cancel units**, to check their work and to reinforce their understanding of the fundamental components of the properties or variables they are working with.
- 2. Students will <u>describe and employ</u> the definitions of such **fluid properties** as mass density, specific weight, specific gravity, viscosity, surface tension, elasticity, vapor pressure and specific heat, and be able to <u>build on</u> these definitions for the rest of the course.
- 3. For fluids at rest, students will <u>understand and calculate</u> how pressure varies with depth, how **hydrostatic forces** vary on submerged faces, why some objects sink and others float, and the factors influencing stability of a floating or immersed body; students will be able to <u>apply equations to predict</u> how hydrostatic forces will act.
- 4. Students will be able to <u>employ</u>, <u>sketch and describe</u> the **control volume** approach and the principle of the **conservation** of mass in solving problems; they will understand how these are used to develop the **continuity equation**. Students will <u>understand</u> how the continuity equation requires conservation of mass in different cross-sections of or at different velocities, and will be able to <u>solve problems</u> based upon those principles.
- 5. Students will <u>understand</u> that **fluids move** in response to differences in pressure: students will be able to <u>describe and</u> <u>calculate</u> how differences in pressure can be caused by elevation (weight); pumps; acceleration or deceleration, or by viscous resistance. Students will understand the **Bernoulli Equation** and be able to <u>solve problems with computations</u> <u>or sketches</u> for many situations, including pitot tubes and flownets.
- 6. Students will <u>review</u> the concept of **momentum**, and will <u>understand</u> how changes in the momentum of fluid are related to forces. Students will understand the **Navier-Stokes Equation** and understand that it relates changes of momentum (acceleration) to shear stresses, gravity and other forces, velocity and pressure; students will be able to <u>solve problems</u> relating momentum, velocity, pressure, and shear stress.
- 7. Students will <u>understand</u> that the **energy equation** combines the effects of mechanical forces (pressure, gravity and shear stress) with heat. They will be able to <u>construct</u> energy grade lines and hydraulic grade lines, and <u>solve other</u> <u>problems</u> wherein energy is transformed among heat, pressure, friction losses, etc.
- 8. Students will <u>understand</u> the principles of **dimensional analysis** and **similitude**, and be able to <u>calculate</u> values of use such numbers as the **Froude number**, **the Mach number**, **Reynold's number** to <u>make general conclusions</u> about modes of fluid motion.
- 9. Students will be able to <u>summarize and describe</u> the importance of **surface resistance and boundary layers** to a myriad of practical situations. Students will <u>understand</u> why a **velocity profile** exists for a flowing Newtonian fluid, and be able to <u>sketch</u> shear stress as a function of position in a tube.
- 10. Students will be able to <u>describe</u> how pressure, velocity, shear stress and momentum affect **flow in pipes**, and will be able to <u>calculate</u> energy losses due to roughness, diameter changes, direction changes, etc.
- 11. Students will be able to <u>describe</u> that **drag and lift** are forces produced by the dynamic action of flowing fluid (unlike buoyant and weight forces), and will be able to <u>calculate</u> drag and lift for certain geometries.
- 12. Students will be able to <u>describe</u> how **open-channel** flow is different from closed-conduit flow, and will be able to <u>calculate</u> specific energy, critical flow, and critical depth. Students will <u>understand</u> how a hydraulic jump occurs.
