

### Landscape Analysis Project: Craig Mountain Wildlife Management Area

For/Range 527 Landscape Ecology

### Your assignment

- Compare and contrast 3 watersheds.
- Predict the changes in vegetation and landscape composition resulting from the 2007 wildfire
- Identify and analyze an additional ecological question

### Craig Mountain Wildlife Management Area in Western Idaho

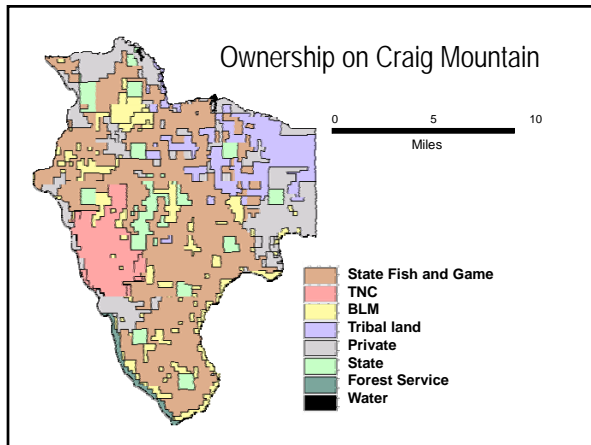

### Biologically Rich

- More than 200 different bird and mammal species are found here.
- Riparian areas are the richest in animal and bird species.
- Some streams support steelhead and red-banded trout.
- Numerous plant taxa found only in Hells Canyon.

### Land Ownership (Percent area)

Idaho Fish and Game	45
Bureau of Land Mgt	10
Forest Service	1
The Nature Conservancy	8
Idaho Department of Lands	9
Nez Perce Tribal lands	11
Private	18

### Management issues

- Changing focus from individual game species to multiple species and biodiversity
- Sensitive species
- Wildfire and the use of prescribed fire

### Invasive species

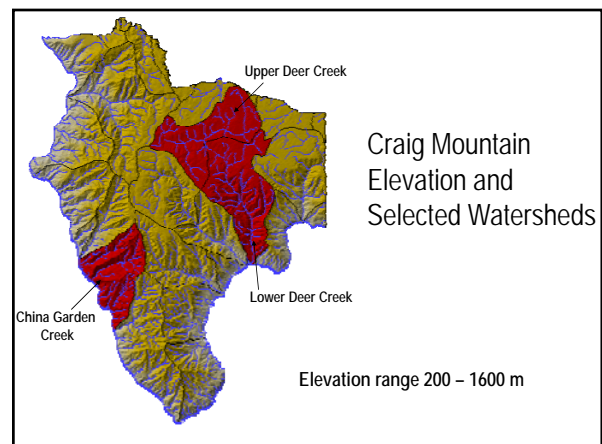

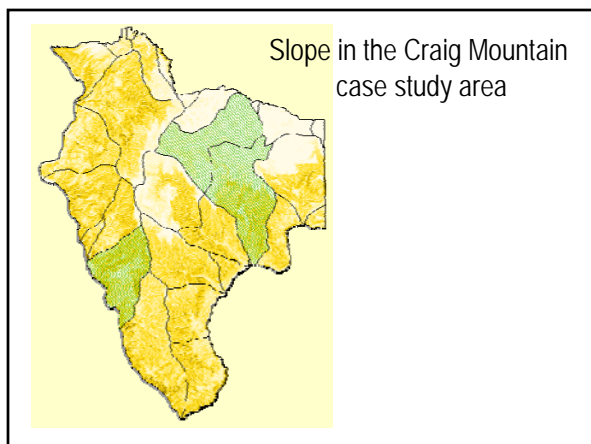

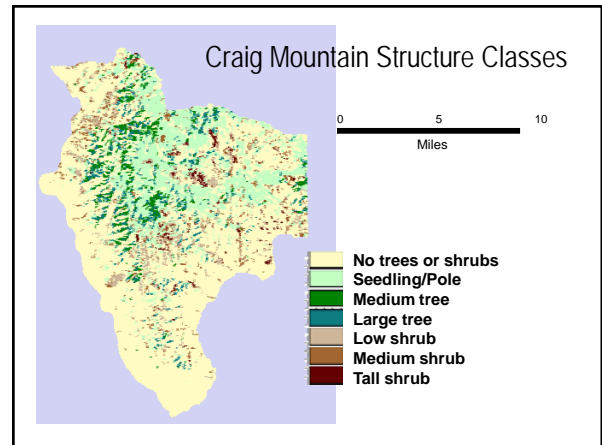

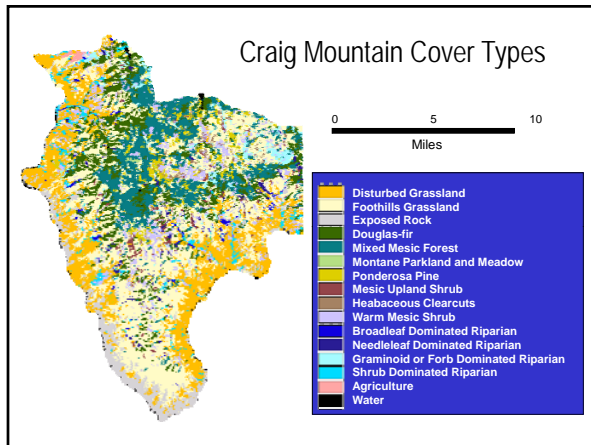

- Weeds threaten ecological integrity
  - grasslands and open forests
  - invertebrate and vertebrate species dependent on those habitats
- Currently, invasive species include: yellow starthistle, common crupina, leafy spurge, Scot's thistle, cheatgrass, and medusahead

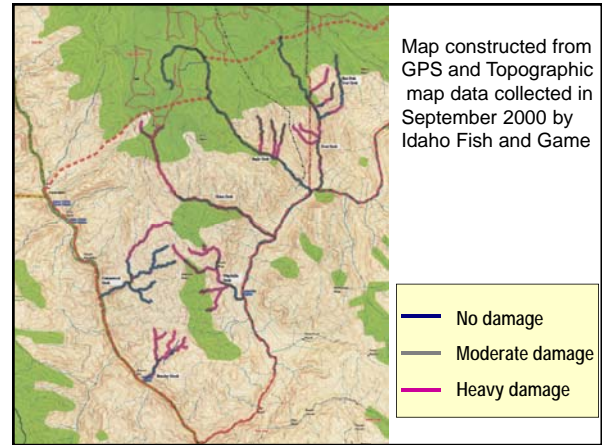

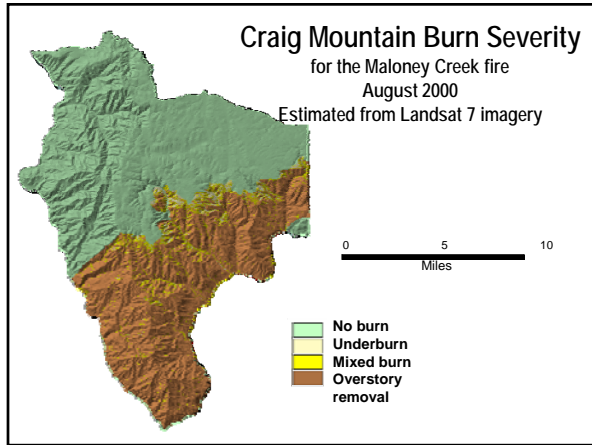

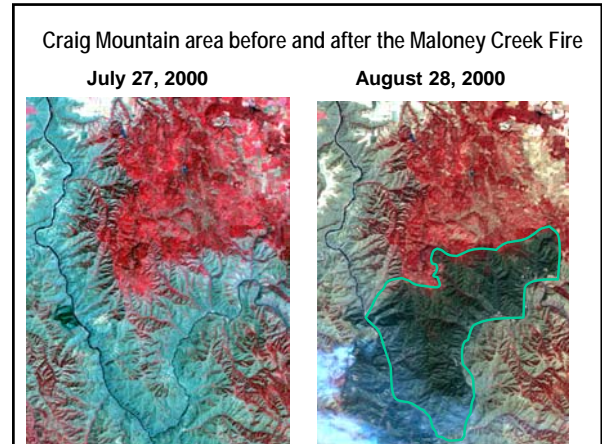

### Legacy of the past

- Riparian and flatter areas were once homesteaded and used for cattle grazing, pasture, crops.
- In the 1930s, there were several post offices, 5 schools and up to 50 homesteads in Hells Canyon.

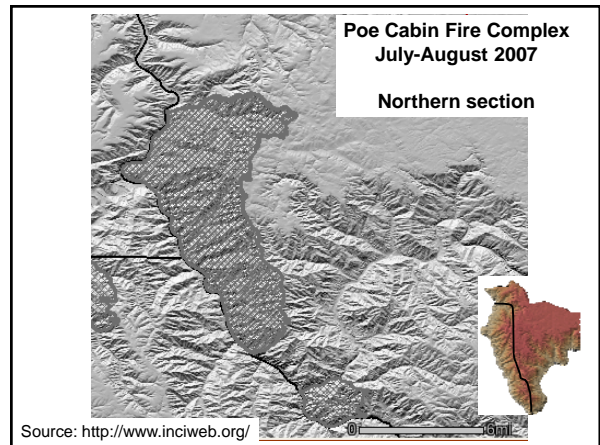

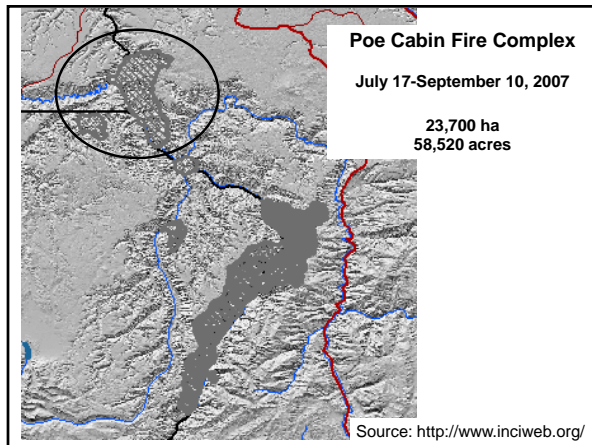

### Data for analysis

- Vegetation
  - Current and historical cover type (1km<sup>2</sup>)
  - Current cover types (30 m)
  - Current tree and shrub size class
- Topography
- Roads and streams
- Soils
- Ownership
- Maloney Creek Fire severity
- Some invasive

Considerations in the development of the team-developed analysis objective:

- Is it a spatial question?
- Is the scale of Craig Mountain WMA, or a subset of CMWMA , adequate for analysis?
- Are there spatial and temporal data to support the analysis?
- Have adequate literature been published to support the analysis?

Normalized Burn Ratio (NBR) –  
A Landsat TM Radiometric Measure of Burn Severity

$$NBR = (R4 - R7) / (R4 + R7)$$
